Abstract

The analytic hierarchy process (AHP) remains a popular multi-criteria decision method. The author has implemented a free, web-based AHP online system with noteworthy features, allowing for the detailed analysis of decision problems. Beside standard functions like flexible decision hierarchies, support to improve inconsistent judgments, alternative evaluation and sensitivity analysis, the software can handle group inputs, calculate group consensus based on Shannon α and β-entropy, and estimate weight uncertainties based on randomized small variations of input judgments. In addition different AHP judgment scales can be applied a posteriori, and alternative evaluation can be done using the weighted sum (WSM) or weighted product model (WPM). This flexibility opens up opportunities to study decision projects under various parameters. The author’s intention was to provide a complete and free software tool for educational and research purposes, where calculations and algorithms are well documented and all input data and results can be exported in an open format for further processing or presentation. The article describes the basic concept and structure of the software and the underlying mathematical algorithms and methods. Challenges and practical experiences during the implementation, validation and productive phase of the software are highlighted.

Keywords

Multi-criteria decision making, Analytic hierarchy process, AHP Software, AHP online system, AHP Group decision making.
1. Introduction

The analytic hierarchy process (AHP) was developed by T. L. Saaty in the 1980 (Saaty, 1980) and remains a widespread multi-criteria decision method (MCDM). Based on pairwise comparison inputs, weights are calculated by finding the dominant right eigenvector (EV) of a positive reciprocal decision matrix. Calculations for simple decision problems can be done with a spreadsheet program (Goepel, 2013), but for more complex decision problems a software tool is needed.

There are several AHP software packages available on the market (see annex), and some of them have been described or were compared in the literature (Ossadnik, Kaspar 2013, Ishizaka, Labib 2009, Siraj et al. 2015), but most of these packages are targeting companies and pursue a business objective. Their focus lies on the application, and less on the methods and algorithms, which are often not fully transparent to users. The author’s intention was to provide a complete and free software tool for educational and research purposes, where methods and algorithms are well documented and validated. As a result, a web-based AHP online system (AHP-OS) was developed and is available in its full functionality to any user for non-commercial purposes.

Implementation of the software was done in PHP, an open source general-purpose, object oriented scripting language that is especially suited to web development. Database functions are implemented using Structured Query Language (SQL), the most widely used database language with available open source database engines like SQLite or MariaDB. The whole package was developed from scratch, using only a few other available open source packages for general supporting functions like sending of e-mails or user login and registration (annex 1).

The functions and features of AHP-OS include

- Flexible definition of decision hierarchies as text input, following a simple syntax with multi-language support using Unicode character coding.
- Weight calculation (hierarchy mode) and alternative evaluation (alternative mode) using the AHP eigenvector method.
- Pairwise comparison input, highlighting the top-3 most inconsistent judgments.
- Partial judgments.
- A posteriori application of different AHP judgment scales.
- Group decision making using weighted geometric mean aggregation of individual judgments (WGM-AIJ).
• Group consensus calculation based on Shannon $\alpha$ and $\beta$-entropy.
• Weight uncertainty estimation using Monte Carlo simulation.
• Sensitivity analysis.
• Weighted sum model (WSM) and weighted product model (WPM) for the aggregation of alternatives.
• Export of input and result data as comma separated value (CSV) files for further processing or presentation in a spreadsheet program.

The software has a modular structure and is implemented using object oriented programming (OOP). It consists of five major objects (classes):

1. $ahp$ class for all basic AHP calculations,
2. $ahpHierarchy$ class for decision hierarchy related functions,
3. $ahpDb$ class for database handling,
4. $ahpGroup$ class for result calculations and
5. $ahpAdmin$ class for all administrative functions like user and project administration.

These classes contain all AHP methods, and in the following we will describe the major functions in more detail.

2. **Decision Hierarchies and Eigenvector Calculations**

The definition of a decision hierarchy in the program is done with plain text input, consisting of a sequence of statements following a simple syntax. This provides different advantages:

• Hierarchy definitions in plain text form can be modified or duplicated by simple copy and paste functions
• They can be archived easily as text files.
• Unicode character coding allows for multi-language support; languages like Chines, Korean, Thai *etc.* are supported.
• Weights can be completely or partly predefined within the hierarchy text. This is useful when weights are already known, *e.g.* from a previous project or derived from other MCDM methods, and AHP-OS is only used for alternative evaluation.
The syntax is defined as follows:

\[
\begin{align*}
\text{<hierarchy>} & \rightarrow \text{<branch>}; \{\text{<branch>;}\} \\
\text{<branch>} & \rightarrow \text{<node>}: \text{<leafs>}, \text{<leafs>}[,\text{<leafs>}] \\
\text{<leafs>} & \rightarrow \{\text{<leaf>} [ = \text{<weight>}]\}
\end{align*}
\]

For all <leafs> in a <branch> the sum of <weight> has to be one. A <node> of the second and any further <branch> has to be one of the <leaf> in <leafs>. Each <node> represents a decision matrix, and the corresponding priority vector’s dimension is the number of <leafs>. Figure 1 shows a simple example of a two level hierarchy. In the first level (main criteria), weights for the two criteria are predefined as 30% and 70%. For the sub-criteria weights are automatically set to the default value \(1/n_{\text{leaf}}\).

![Decision Hierarchy](image)

**Fig. 1** Example of a decision hierarchy. This hierarchy has 2 levels, 3 nodes (AHP priority vectors) and 4 leafs.

This hierarchy in fig. 1 is defined by the following hierarchy text:

AHP-project: Criterion-1=0.3, Criterion-2=0.7;  
Criterion-1: Sub-criterion A, Sub-criterion B;  
Criterion-2: Sub-criterion C, Sub-criterion D;

All methods related to the decision hierarchy are coded in the `ahpHierarchy` class of the software. The class includes the parser to translate the hierarchy text into a multidimensional array. The parser checks for syntax errors and cleans the input text from redundant and impermissible characters. Supporting functions to extract nodes, branches or leafs from the hierarchy are included in this class.

**AHP Eigenvector Method**

Once a hierarchy is defined and stored in the database, weights can be calculated going through the following steps. Each step is coded as a method in the `ahp` class of AHP-OS:

1. Get pairwise comparisons (pwc): `get_pair_comp()`
2. Apply selected AHP judgment scale: calcScale()
3. Fill decision matrix from pairwise comparisons: getMatrixFromPwc()
4. Find the eigenvector using the power method: set_evm_evec()
5. Calculate the dominant eigenvalue from the eigenvector setEvmEval()
6. Calculate the consistency ratio CR: setAlonsoCr()
7. Calculate the inconsistency matrix: get_incon_matrix()
8. Identify and highlight the top three inconsistencies: get_inconsistency()
9. Go back to step 1 until the user submits his judgments.

Figure 2 shows an example of the display of pairwise comparisons to the user.

![Figure 2. Pairwise Comparison Input.](image)

All pairwise comparisons are internally stored in the format

\[ pwc = (a_1, a_2, ..., a_{npc}), (x_1, x_2, ..., x_{npc}) \]  \hspace{1cm} (2.1)

With integers \( a_i \in [0,1] \), \( x_i \in [1,M] \), \( M = 9 \) and \( i = 1 \ldots npc \) with \( npc \) is the number of pairwise comparisons.

\[ npc = \frac{n^2-n}{2}. \]  \hspace{1cm} (2.2)

For \( n \) criteria the \( n \times n \) decision matrix is then filled from \( pwc \). For \( a_i = 0 \) we take \( x_i \), for \( a_i = 1 \) we have to take the reciprocal of \( x_i \). For example, for three criteria with \( pwc = (0,0,1), (3,5,7) \) the decision matrix is

\[ M = \begin{pmatrix} 1 & 3 & 5 \\ \frac{1}{3} & 1 & \frac{1}{7} \\ \frac{1}{5} & 7 & 1 \end{pmatrix} \]  \hspace{1cm} (2.3)

The selected format minimizes redundancy and uses less memory than storing the complete positive reciprocal matrix. The dominant eigenvector (EV) of \( M \) is calculated using the power method (Larsen, 2013). The number of iterations is limited to 20, this is sufficient for an accepted approximation error of 1.E-7.
Calculation of Consistency Ratio

Instead of Saaty’s original consistency ratio calculation, based on the average random consistency index $R_l$, we use the linear fit proposed by Alonso and Lamata (2006) to calculate the consistency ratio $CR$.

$$CR = \frac{\lambda - n}{2.7699 \cdot n - 4.3513 - n}$$  \hspace{1cm} (2.5)

It can also be used for matrices larger than 10 x 10. In case of a decision hierarchy with more than one node, $CR$ of each hierarchy node is calculated, and for the global weights the maximum of all $CR$s is shown by the program.

Calculation of the top-3 inconsistencies

If the consistency ratio exceeds 10%, the software calculates the top-3 inconsistent judgments. We construct the inconsistency matrix

$$e_{ij} = d_{ij} \cdot \frac{w_j}{w_i}$$  \hspace{1cm} (2.6)

and identify the three largest $e_{ij}$. The corresponding pairwise comparisons are then highlighted to the decision makers, allowing them to make some adjustments (Saaty, 2003).

AHP Judgment Scales

Over the last decades a variety of judgment scales, different from Saaty’s fundamental 1 to 9 scale, have been proposed. In AHP-OS pairwise comparisons are stored with their original judgment values (eq. 2.1), we therefore can apply different scales $a posteriori$ and study the effect of different scales on the resulting weights. Ten different scales are implemented and summarized in table 1.

A comparison of these scales, based on weight boundaries and weight ratio, weight uncertainty and weight dispersion, is given by Goepel (2017).
### Table 1. AHP judgment scales implemented in the software.

3. **AHP-OS Database and data structure**

The software uses the PHP data object (PDO) interface to SQL databases. The current implementation can handle two SQL servers, either open source MariaDB, or the public domain SQLite database engine. The implemented database structure comprises of four database tables:

1. **Users**: table for user registration and login. Registered users can be project authors and can store and manage their own AHP projects.
2. **Projects**: table of AHP projects with unique session code, project name, project description and hierarchy definition. Its foreign key is the user name from the table Users.
3. **Judgments (pwc)**: table containing all pairwise comparisons with the decision makers’ name and nodes of the decision hierarchy. Foreign key is the session code from the table Projects.
4. **Alternatives**: table with alternative names. Foreign key is the session code from the table Projects.
This structure minimizes redundancies and keeps the database slim (table 2). In order to identify projects, each project gets a unique 6 character session code. As described before, decision hierarchies are defined with plain text input, and pairwise comparisons are stored in a simple integer format. For group decision making participants’ judgments are stored in the pwc table. Participants don’t need to register as users; they just need to follow a link with the unique session code provided by the AHP project author (registered user). They then can start to input their judgments by opening the link and providing their name. (Field participant in table pwc).

Table 2. SQL database structure.

The ahpDb software class handles the interfacing with the SQL database server. As an example, the following SQL statement:

```sql
SELECT session_code, project_name, count(alt) AS Alt, count(pwpart) AS Part, description,
       date(date_time) FROM projects
LEFT JOIN
  (SELECT DISTINCT pwc.session_code AS pwsc, pwc.participant AS pwpart FROM pwc)
ON projects. session_code = pwsc
LEFT JOIN
  (SELECT alternatives.session_code AS altsc, projects.session_code AS alt FROM projects,
   alternatives WHERE projects.session_code = alternatives.session_code
   GROUP BY alternatives.session_code
  ) ON projects.session_code = altsc
WHERE projects.user_name = :user_name
GROUP BY session_code ORDER BY projects.date_time DESC;
```
will result in a table of all projects for a specified user name, showing the unique project session code, the project name, number of alternatives (if any), number of participants (decision makers) with pairwise comparison inputs, a short project description and the creation date/time of the project. The database does not store results; all results are calculated on the fly using methods in the software class \textit{ahpGroup}.

\textbf{Basic Data structure}

Each node in the decision hierarchy represents a decision matrix with the number of branches as number of criteria. For the example given in fig.1 \textit{AHP project, criterion-1} and \textit{criterion-2} are the nodes of the hierarchy with two branches each, and \textit{sub-criterion A} to \textit{D} build the leaves of the decision hierarchy. In the software we need to calculate the weights of each branch or leaf of all nodes and for all decision makers (participants). The weights (local priorities) are stored in a 3-dimensional array with array keys [\textit{participant}], [\textit{node}] and [\textit{leaf}]. The array key [\textit{participant} = 0] holds the consolidated group results; the array key [\textit{node} = “pTot”] holds the global priorities. This data structure applies to both, hierarchy and alternative evaluation, where for the latter the hierarchy’s leaves become nodes with alternatives as branches. For any calculation the software has to loop through all nodes.

Once the weight calculations are done, the results (local priorities) are inserted into the hierarchy definition text, for example \textit{Criterion-2} becomes \textit{Criterion-2=0.7}. The modified hierarchy text can then be used to define alternatives and be stored as a new project in the database for alternative evaluation.

\textbf{Partial Judgments}

As pairwise comparisons for each node are stored in the pairwise comparisons database table, it is possible for participants to do a partial evaluation, i.e. only give their input for a part of the hierarchy or the alternatives. This can be useful, if a project requires inputs from different experts with specific expertise in selected nodes of the decision hierarchy.

\textit{5. Group decision making}

\textbf{Aggregation of individual judgments}

One of the major advantages of a web based AHP software is that it allows worldwide access. Once a decision hierarchy is defined and stored as a project on the server, decision makers can give their inputs from any location, as long as they have internet access. In AHP-OS each project is identified by a unique
session code, and participants only need a link with this session code to start their pairwise comparisons and submit their judgments. The number of participants is practically unlimited.

In order to consolidate all participants’ judgments, several group AHP aggregation techniques are available, but not all group AHP methods are equally convenient and the selection of the method might depend on the specific application (Grošelj. P et al., 2015). In the current version of the software we decided to use the weighted geometric mean aggregation of individual judgments (WGM-AIJ), as it is the only method that meets several required axiomatic conditions, such as the reciprocal property. We calculate the geometric mean and standard deviation of all K participant’s individual judgments $pwc_k$ to form the consolidated decision matrix $a_{ij}^{cons}$.

Function $pwcGeoMean($spwcArray$)$

Sum over K participants

$$pwcx = \sum_{k=1}^{K} \ln(pwc_k)$$  \hspace{1cm} (5.1)

Square sum over K participants

$$pwcx2 = \sum_{k=1}^{K} [\ln(pwc_k)]^2$$  \hspace{1cm} (5.2)

Geometric mean

$$pwc_{CONS} = \exp\left(\frac{pwcx}{K}\right)$$  \hspace{1cm} (5.3)

Standard deviation

$$pwc_{SD} = \exp\left(\sqrt{\frac{pwcx2 - \frac{1}{K} pwcx^2}{K-1}}\right)$$  \hspace{1cm} (5.4)

Using the pairwise comparison data from eq. 5.3 to fill the consolidated decision matrix we get

$$a_{ij}^{cons} = \left(\prod_{k=1}^{K} a_{ij}\right)^{\frac{1}{K}}$$  \hspace{1cm} (5.5)

The standard deviation $pwc_{SD}$ of individual judgments (eq. 5.4) is used for the estimation of weight variations based on judgment variations.

**Group Consensus**

Although it is always possible to calculate a group result using WGM-AIJ, it does not makes sense in all cases. For example, if we have two opposite judgments for two criteria ($x$ and $1/x$), an aggregation will result in equal weights for both criteria. In fact, there is no consensus (agreement), and equal weights may result in a deadlock situation to solve a decision problem. Therefore, it is necessary to measure the consensus for the aggregated group result. We use Shannon entropy and its partitioning in two independent components (alpha and beta diversity) to derive the AHP consensus indicator. We analyze the priority distribution of criteria among different decision makers. We use the following relations (Goepel, 2013):
Function getShannonBeta($prio, $node)

Shannon beta-entropy
\[ H_\beta = H_\gamma - H_\alpha \]  
(5.6)

Shannon alpha-entropy
\[ H_\alpha = \frac{1}{k} \sum_{i=1}^{k} \sum_{j=1}^{n} (-w_j \ln w_j) \]  
(5.7)

Shannon gamma-entropy
\[ H_\gamma = \sum_{j=1}^{n} (-w_{avg} \ln w_{avg}) \]  
(5.7)

with
\[ w_{avg} = \frac{1}{k} \sum_{j=1}^{k} w_{jk} \]

The similarity measure \( S \) (eq. 5.8) depends on the number of criteria, and we used a linear transformation to map it to a range from 0 to 1 (eq. 5.9)
\[ S = \exp(-H_\beta) = \frac{1}{D_\beta} \]  
(5.8)

\[ S^* = \frac{S - D_{\alpha_{\text{min}}} / D_{\gamma_{\text{max}}}}{1 - D_{\alpha_{\text{min}}}/D_{\gamma_{\text{max}}}} \]

In general \( D_{\alpha_{\text{min}}} = 1 \) and \( D_{\gamma_{\text{max}}} = n \). In the analytic hierarchy process (AHP) minimum alpha entropy \( H_{\alpha_{\text{min}}} = \ln(D_{\alpha_{\text{min}}}) \) is a function of the maximum scale value \( M \) (\( M = 9 \) for the fundamental AHP scale) and the number of criteria \( n \) (eq. 5.9).
\[ H_{\alpha_{\text{min}}} = -\left(\frac{M}{n+M-1}\right) \ln\left[\frac{M}{n+M-1}\right] - \left(\frac{n-1}{n+M-1}\right) \ln\left[\left(\frac{1}{n+M-1}\right)\right] \]  
(5.9)

Maximum gamma entropy \( H_{\gamma_{\text{max}}} = \ln(D_{\gamma_{\text{max}}}) \) is
\[ H_{\gamma_{\text{max}}} = \ln(n) \]  
(5.10)

Function hamin($nCrit, $mScale)

The correction factor \( cor \) is

Function ahpShannonCor($nCrit, $mScale)

\[ cor = \exp[H_{\gamma_{\text{max}}} - H_{\alpha_{\text{min}}}]^{-1} = D_{\alpha_{\text{min}}}/D_{\gamma_{\text{max}}} = \frac{\exp(H_{\alpha_{\text{min}}})}{n} \]  
(5.11)

The AHP consensus indicator is based on the relative homogeneity \( S \)

Function relHomogeneity($dBeta, $dBetaMin)

\[ S = \frac{1}{D_\beta} - \frac{1}{D_{\beta_{\text{min}}}} \]  
(5.12)
AHP Group Consensus Indicator

Function getConsensus($prio, $node, $iScale)

\[
S^* = \left( \frac{1}{\exp(H_\beta) - \exp(H_{\gamma_{\text{max}} - H_{\gamma_{\text{min}}}})} \right) / \left( 1 - \frac{1}{\exp(H_{\gamma_{\text{max}} - H_{\gamma_{\text{min}}}})} \right) \tag{5.13}
\]

\[
S* = \frac{1/D_\beta - \text{cor}}{1 - \text{cor}} \tag{5.14}
\]

The consensus of the complete hierarchy is calculated as weighted arithmetic mean of the consensus of all hierarchy nodes (categories); for alternatives we take the consensus indicator of the consolidated alternative evaluation matrix weighted with the global priorities.

The consensus indicator ranges from 0% (no consensus) to 100% (full consensus). The whole range is categorized into five categories according table 3.

<table>
<thead>
<tr>
<th>(S^*)</th>
<th>Consensus</th>
</tr>
</thead>
<tbody>
<tr>
<td>≤ 50%</td>
<td>Very low</td>
</tr>
<tr>
<td>50% - 65%</td>
<td>low</td>
</tr>
<tr>
<td>65% - 75%</td>
<td>moderate</td>
</tr>
<tr>
<td>75% - 85%</td>
<td>high</td>
</tr>
<tr>
<td>≥85%</td>
<td>Very high</td>
</tr>
</tbody>
</table>

Table 3. Interpretation of AHP consensus.

6. Weight Uncertainties

As shown by Goepel (2017) weight uncertainties due to rounding of the judgment to integers can exceed 10%, and could impact the results of a decision. In order to get an estimation of uncertainties, we generate \(NVAR\) randomized variations of the original judgments with

Function generateRandPwc($pwc, $n, $dx)

\[
pwcr_j = (a_1, a_i, ..., a_{nPC}), (x_1 + \Delta x_1, ..., x_i + \Delta x_i, ..., x_{nPC} + \Delta x_{nPC}) \tag{6.1}
\]

With \(a_1 = 0\) for \(x_i + \Delta x_i \geq 1\), and \(a_1 = 1\) for \(x_i + \Delta x_i < 1\),

where \(\Delta X\) are randomly uniform distributed values (-0.5, 0, +0.5).

\[
\Delta X \sim 0.5 \cdot U(-1, +1)/\sqrt{K} \tag{6.2}
\]
and $K$ is the number of participants.

For each variation $pwcr_j$ the eigenvector solution $w_j$ and consistency ratio $CR$ is calculated. We then capture the maximum and minimum of the weights for all $CR < 0.25$.

Function uncertainty($pwcr$, $ahpH$, $siScale$, $sdFlg$, $hierMode$)

\[
\Delta w_+ = (w_{max} - w) = \left( \max[w_j = EV(pwcr_j)]_{j=1}^{NVAR} - w \right) \quad (6.3)
\]

\[
\Delta w_- = (w - w_{min}) = \left( w - \min[w_j = EV(pwcr_j)]_{j=1}^{NVAR} \right) \quad (6.4)
\]

Figure 3 shows a typical example of weight uncertainties of a project with $x$ criteria using the standard AHP 1 to 9 scale.

![Figure 3](image)

Figure 3. Calculated weights for a project with 7 criteria with weight uncertainties due to rounding.

Alternatively, users can also display uncertainties using the standard deviation of judgments $pwcsd$ (eq. 5.4), if there are more than one participant. It gives, in addition to the AHP consensus, an idea about the weight variations based on participants’ judgment variations.

\[
pwcr_j = \left( a_1, ... a_i, ..., a_{npc} \right), \left( x_1 \Delta x_1, ..., x_i \Delta x_i, ..., x_{npc} \Delta x_{npc} \right) \quad (6.5)
\]

\[
\Delta X \sim N(\mu, \sigma^2) \quad (6.6)
\]

\[
\Delta x_i = \exp\left(\frac{1}{2} \log pwcsd \cdot \Delta X\right) \quad (6.7)
\]

Overlap
The program provides a list of criteria or alternatives overlapping within the estimated weight uncertainties. Overlapping criteria or alternatives should get the same ranking, as they cannot be differentiated within the uncertainties.

7. Alternative Evaluation

Weighted Sum and Weighted Product Model

Function $\text{calcPrioTotal}(k, pGlb)$

In AHP the preference $P_i$ of alternative $A_i$ is calculated using the weighted sum model (WSM):

$$P_i = \sum_{j=1}^{n} a_{ij} w_j$$

with $W_j$ the weight of criterion $C_j$ and $a_{ij}$ the performance measure of alternative $A_i$ with respect to criterion $C_j$. Performance values are normalized.

$$\sum_{j=1}^{n} a_{ij} = 1$$

In the software users can also select the weighted product model (WPM), where alternatives are aggregated using the product instead of the sum

$$P_i = \prod_{j=1}^{n} a_{ij} w_j$$

Some of the first references to this method are due to Bridgman (1922) and Miller and Starr (1969).

8. Sensitivity Analysis

Sensitivity analysis is a fundamental concept in the effective use and implementation of quantitative decision models, whose purpose is to assess the stability of an optimal solution under changes in the parameters. Sensitivity analysis (Triantaphyllou, 1997) will answer two questions:

- Which is the most critical criterion, and
- Which is the most critical performance measure,

changing the ranking between two alternatives?

The most critical criterion is defined as the criterion $C_k$ with the smallest absolute ($\delta_{k,i,j}^{abs}$) or relative ($\delta_{k,i,j}^{rel}$) change of the current weight $W_k$ by the amount of $\delta_{k,i,j}$ changing the ranking between the alternatives $A_i$ and $A_j$.

The most critical measure of performance is defined as the minimum absolute or relative change of the current value of $a_{ij}$ such that the current ranking between alternative $A_i$ and $A_j$ will change. Calculation is different for WSM and WPM.
Weighted Sum Model (WSM)

To find the *most critical criterion* we calculate for each pair of alternatives $A_i, A_j$, with $i = 1$ to $n$ and $i < j$

$$
\delta_{i,j,k}^{abs}(A_i, A_j, W_k) = \frac{P_j - P_i}{a_{jk} - a_{ik}}
$$

(8.1)

with

$$
|\delta_{i,j,k}^{abs}(A_i, A_j, W_k)| < W_k
$$

and

$$
\delta_{i,j,k}^{rel}(A_i, A_j, W_k) = \delta_{k,i,j}^{abs} / W_k
$$

To find the *most critical measure of performance* we calculate for all alternatives $A_i$ and $A_k$ with $i \neq k$ and each criterion

$$
\delta_{i,j,k}^{abs}(W_j, a_{kj}, a_{ij}) = \frac{P_i - P_k}{P_i - P_k + W_j(a_{kj} - a_{ij} + 1)}
$$

(8.2)

with

$$
|\delta_{i,j,k}^{abs}(W_j, a_{kj}, a_{ij})| < W_j
$$

and

$$
\delta_{i,j,k}^{rel}(W_j, a_{kj}, a_{ij}) = \delta_{k,i,j}^{abs} / a_{ij}
$$

(8.3)

Weighted Product Model (WPM)

To find the *most critical criterion* for each pair of alternatives $A_i, A_k$, with $i = 1$ to $n$ and $i < k$ we calculate

$$
\log \left( \prod_{y=1}^{n} (a_{iy} / a_{ky})^{W_y} \right)
$$

(8.4)

and

$$
\delta(A_i, A_k, W_j) = \frac{\log \left( \prod_{y=1}^{n} (a_{iy} / a_{ky})^{W_y} \right)}{\log(a_{ij} / a_{kj})}
$$

(8.5)

with

$$
\delta^{abs}(A_i, A_k, W_j) < W_j
$$

Then we look at the smallest

$$
\delta^{rel}(A_i, A_k, W_j) = \frac{\delta^{abs}}{W_j}
$$

(8.6)

To find the *most critical measure of performance* for the WPM we calculate for all alternatives $A_i$ and $A_k$ with $i \neq k$ and each criterion

$$
\delta^{rel}(A_i, A_k, W_j) = \left( 1 - \frac{W_j}{\sqrt[\Delta_k]{A_k / A_i}} \right)
$$

(8.7)
and look for the smallest \( \delta^\text{rel}(A_i, A_k, W_j) < 1 \) \hspace{1cm} (8.8)
and
\[ \delta^\text{abs} = a_{ij} \delta^\text{rel} \] \hspace{1cm} (8.9)

**Program Output for Sensitivity Analysis**

Depending on the results, the program will then display the following text output

- The solution for the top alternative \( A_s \) robust.
- The percent-top critical criterion is \( C_y \), a change from \( y\% \) by absolute \( dy\% \) will change the ranking between alternatives \( A_i \) and \( A_k \).
- The percent-any critical criterion is the same as above.
- The percent-any critical criterion is \( C_z \), a change from \( y\% \) by absolute \( dz\% \) will change the ranking between alternatives \( A_i \) and \( A_j \).
- The percent-any critical performance measure is for alternative \( A_i \) under criterion \( C_z \). A change from \( x\% \) by absolute \( dx\% \) will change the ranking between \( A_i \) and \( A_j \).

When exporting the results, the complete sensitivity tables (eq. 8.1 and 8.2 or eq. 8.5 and 8.9) will be exported.

**9. Data Export**

AHP-OS is intended for educational and research purposes, therefore it is important to provide an extensive possibility of data export for further analysis or presentation. The most common and universal format is the comma separated value (csv) text format. It can be easily imported into most spreadsheet programs, independent from the operation system. The software provides download functions for input data (hierarchy, decision matrices), local and global weights with estimated uncertainties, alternative tables and sensitivity analysis.

**10. Software Validation**

Coding and implementation of the complete AHP-OS software package resulted in approximately ten thousand lines of code; therefore testing and validation became essential. With each new release the author goes through a pre-defined checklist for unit, integration and system testing. In addition, in order to ensure that the user can rely on the accuracy of the program results, test cases were designed for black box testing. We compare program results with manually calculated results and results published in the literature.
A simple test case with known results is the case, where we judge one criterion \( x \)-times more important than all others. The weight for this criterion has to be (Goepel, 2017)

\[
W_{\text{AHP}} = \frac{x}{x+n-1}
\]  

(10.1)

For example, if all criteria are equal \((x = 1)\), it follows that \(W_{\text{AHP}} = 1/n\), and for four criteria, with one criterion nine times more important than all others, it follows \(W_{\text{AHP}} = \frac{9}{12} \) or 75%.

In a next step we can apply different scales functions according table 1 by replacing \( x \) with the scaled value \( c \).

Group decision making can be validated by verifying that the elements of the consolidated group matrix show the geometric mean of the elements of the individual matrices.

Testing the AHP consensus indicator is done by simulating \( k \) participants for a hierarchy with \( k \) leafs, and each participant judges one different leaf extreme more important than all others. The resulting consensus should show 0% for all scales.

As a test case for weight uncertainties we use the derivation of eq. 10.1

\[
\frac{dw}{dx} = \frac{n-1}{(x+n-1)^2}
\]  

(10.2)

With \( n = 2, dx = 0.5 \) and \( x' = x \pm dx/2, x > 1 \) we get

\[
\Delta w(+) = \frac{0.5}{(x+1.25)^2}
\]  

(10.3)

\[
\Delta w(−) = \frac{0.5}{(x-0.75)^2}
\]  

(10.4)

For example, for two criteria A and B with A three times more important than B, we get \( w = 75\% \) with \( \Delta w(+) = 2.8\% \) and \( \Delta w(−) = 3.6\% \).

Alternative evaluation using the weighted sum or weighted product model can be verified exporting the results and using a spreadsheet program and its SUMPRODUCT function.

As a test case for sensitivity analysis we use a spreadsheet program with exported data and subtract \( \delta_{\text{abs}} \) from the original weight \( W_j \)

\[
W'_k = W_k - \delta_{\text{abs}}
\]  

(10.5)
Using WSM eq. 7.1 or WPM eq. 7.3 for alternative aggregation the performance measure of alternative $A_i$ should now equal that of alternative $A_j$. In a similar way we can calculate

$$a'_{ij} = a_{ij} - \delta_{\text{abs}}$$

(10.6)

and alternative $A_i$ should have the same performance measure as alternative $A_k$. For WSM we have to renormalize $a_{ij}$ according eq. 7.2.

11. Experiences and Outlook

AHP-OS was originally released in 2014. Features described in this paper were developed gradually over the last three years. With the currently implemented functionality the software tool has reached a state, where it covers most of the possible options for the classical analytic hierarchy process. It allows for a wide range of parameter variations to analyze and study a specific project under different aspects. This and the possibility of transparent data export makes it an ideal tool for study, education and further research.

Up to the date of writing this paper more than 5000 users have registered for the software, and on average there are at least 500 active users over a three months period. The AHP projects handled with AHP-OS cover a wide range of applications like healthcare, climate, risk assessment, supplier selection, hiring, IT, marketing, environment, transport, project management, manufacturing or quality assurance. Numerous projects are used to acquire group inputs, the number of participants goes up to 320 in single projects. Multi-language support is utilized for languages like Chinese, Korean, Russian, Hebrew, Greece, Thai, Vietnamese or Arabic. Lecturers at universities make use of AHP-OS as a tool for their students when teaching multi criteria decision making methods.

Overall the number of software bugs could be kept reasonable low, more often users’ feedback and questions relate to the understanding of the AHP and can be solved straightforwardly. The main challenges in maintaining the software are updates of the underlying open source tools due to security reasons, or smaller updates requested by users. Because of the complexity of the software they always require extensive testing and validation.

A few extensions of AHP-OS are under consideration for the future, for example a selection of different group aggregation techniques in addition to WGM-AIJ. As a major extension a cluster analysis of group consensus is planned. The concept of Shannon entropy and its partitioning in alpha- and beta-entropy opens the possibility to identify clusters of sub-groups with high consensus within a group of decision makers. This could help to gain a deeper insight into group decision making processes.
